

What if your code could prove it's the same code, every time?

TEE attestation, explained without the cryptography
jargon.

THE PROBLEM

When payroll math runs on a server, you trust the server operator.

What if you didn't have to?

TEE IN ONE SENTENCE

A CPU-level secure enclave where memory is encrypted and code execution is measured.

The CPU itself enforces it. Even the OS can't peek inside.

The specific TEE Million uses.

- Memory encryption – RAM is ciphertext to outside code
- Integrity protection – tampering detected
- Attestation – enclave signs proof of what's inside

ATTESTATION

The enclave signs a measurement of its own code.

You verify the signature.

You know the exact code that ran.

Not 'trust the vendor'. Math.

WARM WORKLOAD PATTERN

Run one long-lived enclave. Pin the measurement. Sign inputs with Ed25519.

~200x faster than spinning a new enclave per request.

This is the pattern Civitas uses for payroll runs.

WHAT THIS GETS YOU

Civitas runs payroll compute inside nilCC.

Pinned measurement. Ed25519-signed inputs. Our ops team cannot tamper with payroll math.

Period.
